Market risk – Impact of market moves.

VaR computation complications:

- Intermediate events.
- Formulas become impossible.
- Model selection and parameter estimation:
 - Mean hard to estimate.
 - Variance is easier.
 - Weighted averaging is useful.
 - Use GBM for nonnegative risk factors.
 - Use ABM for everything else.
 - Maybe factor models.

Types of VaR:

- Parametric – Formulas for approximations.
- Historical – Monte Carlo with historical perturbations. applied
- Monte Carlo – Fit models to risk factors and calculate VaR by simulation.

Mean and variance of sum of lognormals:

$$V_t = aS_{1,t} + bS_{2,t}$$

$$dS_i = \mu_i S_i dt + \sigma_i S_i dW_i$$

$$dW_1 dW_2 = \rho dt$$

$$E[S_{1,t} S_{2,t}] = S_{1,0} S_{2,0} e^{(\mu_1 + \mu_2 + \rho \sigma_1 \sigma_2)t}$$

$$E[V_t] = aS_{1,0} e^{\mu_1 t} + bS_{2,0} e^{\mu_2 t}$$

$$E[V_t^2] = a^2 S_{1,0}^2 e^{(2\mu_1 + \sigma_1^2)t} + b^2 S_{2,0}^2 e^{(2\mu_2 + \sigma_2^2)t} \\ + 2abS_{1,0} S_{2,0} e^{(\mu_1 + \mu_2 + \rho \sigma_1 \sigma_2)t}$$

$$\text{var}[V_t] = E[V_t^2] - E[V_t]^2$$

- 7 Summary

Introduction

Post-crisis, regulations regarding model risk management have been greatly expanded [[OCC11](#); [Bas13](#)].

Pre-crisis:

- Focus on model validation.

Post crisis:

- Focus on model risk management.

Model risk management requirements (as per [[OCC11](#)]):

- Effective governance.
- Robust model development, implementation and use.
- Sound model validation practices.

Post crisis, model risk management is the **fastest growing** area in finance.

Additional references: [[OCC14](#)], [[FED11b](#)], [[FED09](#)], [[Bas13](#)], [[FED11a](#)].

Governance, policies and controls:

- Large part of regulations.
- Ensuring structure of firm and policies in place promote sound model risk management.
- Avoid conflict of interests and moral hazards.
- To promote a firm-wide “safety first” mindset.

Requirements:

- Independent risk control unit.
- Strong board and senior management support and respect for risk management.
- Regular auditing of risk management and general firm practices.

Board and senior management:

- Must be actively involved in the risk control process.
- Must regard risk control as essential.
- Must devote significant resources to it.
- Must insure that risk reports are reviewed at a level that can enforce risk reductions.
- Must review risk reports on a monthly basis.

Policies:

- Firm-wide risk appetite statement.
- Risk management practices and policies must be documented, sound, and adhered to.
- All aspects of model risk management must be covered.
- Testing and accuracy must be emphasized.

Summary

References

Pre-deployment risk management = software development best practices:

1. A clear statement of purpose for the model (i.e. a requirements document).
2. Design documentation.
3. Data analysis.
4. Testing.
5. System analysis and testing.

The design document justifies the choice of model, including:

- Justification of model choice by reference to published research and/or sound documented industry practices.
- Explanation of the mathematical specification and numerical techniques in detail.
- Analysis of the assumptions, merits and limitations, including the extent to which risks are captured.
- Comparison with alternative approaches.
- Documentation and validation of subjective components (such as fine tuning based on expert knowledge).

Data

Summary

References

Data is a critical component.

- Problematic data = questionable results.

Data analysis includes:

- Documentation of the data being used.
- Rigorous assessment of the data quality.
- Demonstration that the data is suitable for the model and consistent with the theory and methodology.
- Identification, justification and documentation of all proxies used.
- Documentation and analysis of all assumptions made when adjusting data (data cleaning, data smoothing, data averaging, etc).

Code review

- Important component of validation.

Look for:

- Bugs.
- Design weaknesses.
- Hidden assumptions.
- Common coding errors (e.g. equality comparison between floating point numbers).
- Unit tests.
- Appropriately chosen algorithms.
- Each module/function/routine has a simple, well defined purpose.
- Separation of data gathering from calibration from computation.

Robustness testing:

- Testing the stability and robustness of the model (sensitivity to changes in market conditions and to deal specifications).
- Assessment of the limitations of the model (parameter ranges, assumptions, etc).
- Assessing behavior over a large range of inputs.
- Assessing impact of assumptions.
- Identifying situations where the model performs poorly or becomes unreliable.
- Testing under actual circumstances and with a variety of market conditions, extreme values, etc.
- Assessing impact of model results that feed other models.
- Application of a variety of tests (statistical, accuracy, etc).

Each stage requires review:

- Review by independent teams not vested in the model release.
 - The model design committee
 - The model validation team
 - Senior management
 - Board of directors
- Entire process is subject to audit.
- Implementation does not begin until data selection, the model, and the numerical methods have been approved.
- If model doesn't pass, shortcomings must be addressed and model must be revised.

Once a model is deployed, feedback must be obtained regarding the performance of the model. The development team must:

- Elicit and incorporate feedback from model users.
- Elicit and incorporate feedback from independent sources.
- Confirm that reports produced are clear and comprehensive.
- Reports produced should indicate and adjust for accuracy and uncertainty in results, either by output of ranges of results, or by making results more conservative.
- Confirm that users of the models understand the model limitations, uncertainty and inaccuracy.

Good change management is also required:

- Changes must be justified, logged and tested.
- Testing and revalidation, based on the magnitude of the change.
- Small implementation changes: unit testing and review.
- Large changes: full documentation, review, and testing akin to new model development.

Similarly, changes in use of the model must be documented, justified and tested as above.

Data

Summary

References

Model validation:

- Verifying that the models are performing as expected.
- Verifying that the models are in line with their design objectives and business uses.
- Carried out by an independent the model validation team.

Guiding principal - “effective challenge”:

- Objective, informed parties.
- Applying critical analysis to models and their use.
- Identifying model limitations.
- Findings are taken seriously and promptly enacted upon.

Special cases

Behavior

Robustness

Backtesting

Data

Summary

References

The regulations require sound management practices as well:

Model validation must:

- Be independent from model development and model use.
- Have no stake in model validity.
- Be supported by a separate reporting line from users of the model and from model development.
- Have a high level of expertise and experience.
- Have a significant degree of familiarity with the business lines using the model and the intended uses.

Validation management

There are also requirements on the reporting structure and the corporate culture:

- Incentives and compensation of the model validation team must promote high quality, critical work.
- The corporate culture must encourage objective thinking, and the questioning and challenging of ideas.
- The model validation team must have explicit authority to challenge developers and users and to elevate issues and deficiencies.
- The model validation team must report to someone with sufficient influence to ensure that issues and deficiencies are quickly mitigated.
- Management must disallow the use of a model if significant deficiencies are found.

Core activities of model validation:

- Evaluation of conceptual soundness.
- Ongoing monitoring.
- Outcome analysis and backtesting.

We will review each aspect in detail.

Conceptual soundness

Evaluation of conceptual soundness:

- Careful review of documentation by independent experts.
- Ensure that model is appropriate for task at hand.

Goals and activities:

- Assess the quality of the model design and construction.
- Review the documentation and empirical evidence justifying the model and it's validity and accuracy.
- Ensure sound judgment was used in model development.
- Review model *before* it goes into use.
- Review model whenever material changes are made.
- Ensure documentation and testing done during model development was adequate and valid.
- Perform sensitivity analysis to ensure the model is stable in the face of multiple simultaneous changes of model inputs.
- Develop a clear action plan based on testing and evaluation results, such as modifying model properties, putting less reliance on its outputs, placing limits on model use, or developing a new approach.

Ongoing monitoring

Backtesting

Data

Summary

References

Ongoing monitoring:

- Critical to ensuring that the model continues to perform well in the face of day to day changes in:
 - products,
 - exposures,
 - firm activities, and
 - the markets.

Goals:

- Ensure that the model is appropriately implemented.
- Ensure that model is being used as intended.
- Ensure that model is performing adequately in current scope and market.

Ongoing monitoring

Ongoing monitoring requirements:

- Design a program of ongoing testing and evaluation, including verification and bench marking.
- Model limitations should be regularly reassessed.
- Verify internal and external data inputs continue to be accurate, complete and consistent with the model purpose and design.
- Ensure rigorous quality and change control procedures are applied to the code.
- Perform system integration testing.
- Perform ongoing sensitivity, robustness and stability testing.
- Monitor model input values to detect when inputs start to approach model limitations.
- Monitor overrides applied to models. High rates of overrides indicate a model needs revision or redevelopment.
- Compare inputs and output to other sources.
- Compare model outputs to other models.

In all cases which indicate the potential deterioration of model performance, issues must be escalated and addressed.

Outcome analysis activities:

- Document tests run, justification for selected tests, testing results, and analysis of testing results.
- Confirm that model forecasts are accurate.
- Confirm that model outputs conform to expected range of outcomes.
- For VaR, do backtesting - confirm that percentage of times VaR is exceeded (VaR exceptions) are close to VaR percentile, that exceptions are not clustering, or growing, test a variety of percentiles, etc.
- For other models, develop tests analogous to VaR backtesting tests, such as P&L attribution tests for pricing models.

Outcome analysis scope:

- Thoroughness of testing must be commensurate with the impact of model failures.
- Tests must be tailored to the situation – type of model, usage of model, impact of model outputs. No test applies to all situations.
- Apply regression tests to changes in data, code or other adjustments to confirm that changes improve outcomes. If changes do not outperform, additional changes or a wholesale redesign are called for.
- Develop early warning tests for long forecast horizons (i.e. don't wait for long forecasts to prove unreliable).

Testing numerical code

- 1 Review
- 2 Introduction
- 3 Governance, policies and controls
- 4 Model development
- 5 Model validation
- 6 Testing numerical code
 - Failure modes
 - Special cases
 - Behavioral confirmation
 - Robustness testing
 - Backtesting
 - Data testing
- 7 Summary

Testing numerical code

Testing of numerical software is especially difficult:

- Non-numerical software:
 - Fairly straight forward.
 - Errors are usually obvious.
- Numerical software:
 - Output is just a numerical value
 - Hard for a person to judge if the value is correct.

Need catalog of testing techniques. We will discuss:

- Failure modes.
- Use of special cases.
- Confirming expected behavior.
- Robustness testing.
- Backtesting.
- Data testing.

Data

Summary

References

It is important to be familiar with the failure modes of numerical computations.

Ask during development and during code reviews:

- Where can underflows and overflows occur and how will they propagate through the calculation?
- How do approximations propagate through the calculations and impact results?
- Are sums or differences being computed of values that are too close together or too far apart?
- Are we following best practices for numerical code and numerical programming?

Robustness

Backtesting

Data

Summary

References

Sums and differences:

- Important when approximating derivatives using the difference in function values.
- $B - A = B$ if B is too large relative to A .
- $B - A$ is noise if A and B are close but noisy (and noise is independent).
- Errors can increase or decrease depending on whether they are positively or negatively correlated.

Approximations

Numerical code is always an approximation.

Finite difference and lattice methods:

- Price functions are piecewise linear (or log-linear, or exponential, etc) with respect to at least some of the inputs.
- Difference derivatives for small Δx :
 - the slope of the piece in question
 - jumps between pieces
- Second derivatives:
 - Zero (or otherwise misleading results) when the interval lies on one of the pieces
 - Spikes when the interval straddles a corner.

“Exact” solutions:

- Still have limited accuracy.
- Errors can grow as the number of arithmetic operations grows.

General Greeks:

- Pick Δx to balance convexity error and cancellation.

Example price plot

Consider computing an option price with a coarse lattice. The price graph appears reasonable:

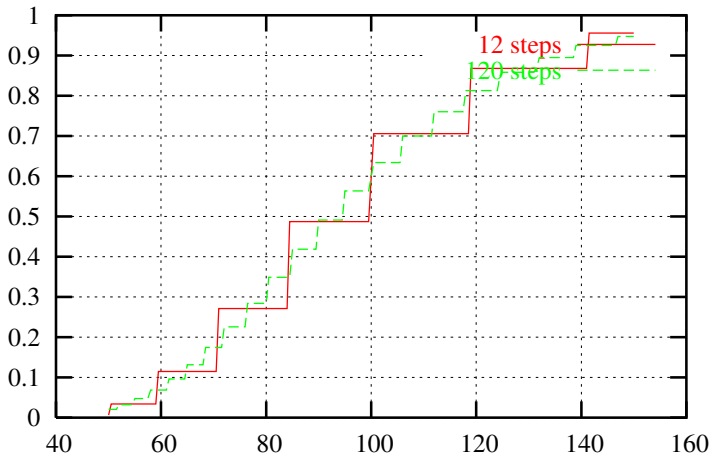

Option value, 1 yr opt, 30% vol, 3% risk free rate

Difference derivative plot

Computing and graphing the difference derivative with a step size of 0.01 highlights that the calculation is piecewise linear, and that delta requires care:

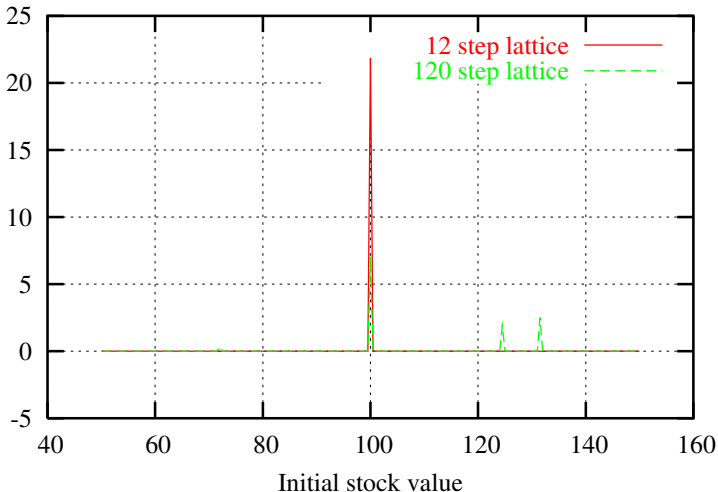

dC/dS , 1 yr opt, 30% vol, 3% risk free rate, $h=.01$

2nd order difference derivative plot

Gamma will be complete garbage unless action is taken:

ddC, 1 yr opt, 30% vol, 3% risk free rate, $h=.01$

Robustness

Backtesting

Data

Summary

References

Knowledge and information about special cases can help to confirm the correctness of model implementations.

- Replicate numbers quoted in the literature.
- Compare to known solutions.
- Compare to simpler models and simpler cases.
- Compare to a different implementation (prototype, Monte Carlo, older version, etc).

Comparisons:

- Confirm identical behavior when complex model reduces to simpler model.
 - Zero volatility
 - Zero strike
 - Flat volatility
 - Zero vol of vol
 - ...
- Confirm behavior of complex model relative to simpler model.
 - Using knowledge that more complex model prices certain options higher.
- Compare different implementations:
 - Prototype.
 - MC vs finite difference.
 - New version vs validated older version.
 - Internal Greeks vs bump and recompute.

Facts that one knows about models should be checked.

- Document facts.
- Confirm that implementation exhibits the predicted behavior.

Examples:

- Monotonicity of the price as a function of various inputs.
- Limiting case behavior.
- Reasonable behavior between limiting cases.
- Comparisons between different cases.
- Confirm model implications hold.
- Internal consistency tests.
- Plotting results.

Data

Summary

References

Limiting cases:

- Call option prices tending to spot or zero as strike goes to zero or infinity.
- Price goes to intrinsic as vol goes to zero.
- Reasonable behavior between limiting cases.

Comparisons between different cases:

- American price \geq Bermudan \geq European.
- Getting European price from American pricer on a European option.

Confirm model implications hold:

- Put-call parity holds.
- Arbitrage is not violated.
- Dominating contracts have higher prices.

Internal consistency tests:

- Forward distributions and conditional distributions match analytic results
- Forward rates of different tenors make sense.

Plotting:

- Plot and inspect prices and first and second order difference derivatives.
- First derivative will confirm or refute monotonicity.
- Pricing noise will show up in 1st and 2nd derivatives.

Convergence testing:

- Monte Carlo error estimates.
- Price as a function of number of scenarios.
- Price as a function of grid size (for finite difference).

Should yield an estimate of accuracy when running in production.

Inversion testing:

- Confirm that numerical inversions work.
- Check error bounds from simple root finders.
- Confirm calculated solutions are in fact solutions.
- Confirm calibrated models reprice inputs.

In good models, parameters are stable.

- Small perturbations of model inputs should not lead to large changes in internal model parameters.
- Internal model parameters should be relatively stable over time.
- Model outputs should be relatively stable over time. goes for model outputs.

Failures could be due to numerical method instabilities or model inappropriateness or instability.

There are a number of different sorts of backtests that can be used to compare models.

1. P&L attribution.
2. VaR backtesting.
3. Hedge effectiveness.

P&L attribution

P&L attribution:

- Confirms that modeled price changes match observed price changes.
- Discrepancies can indicate missing risk factors

Methodology:

- Price portfolio each day.
- Compare computed price changes to actual price changes.
- Expect unexplained P&L to have zero mean and low variance (relative to actual P&L variance).
- Final FRTB Basel rule [Bas16]:
 - Mean $\pm 10\%$ constitutes a breach.
 - Relative variance $> 20\%$ constitutes a breach.
 - Reject model and revert to standard approach if ≥ 4 breaches of last 12 monthly calculations.

Data

Summary

References

VaR testing:

- Compare actual P&L to VaR to confirm accuracy of VaR.
- P&L exceeding VaR is an exception.
- Expect exceptions in $(1 - p)\%$ of the cases for p percentile VaR.
- Final FRTB Basel rule [Bas16]:
 - Compute exceptions daily over last 250 days.
 - Excessive exceptions increase capital requirements.
 - > 30 97.5% VaR exceptions, must revert to standard approach.
 - > 12 99% VaR exceptions, must revert to standard approach.
- For more sophisticated tests and result analysis, see Cogneau [Cog15].

Hedge effectiveness.

- Backtest hedging strategy for a variety of options.
- Compute P&L.
- Nonzero mean means model is biased.
- Large variance means poor model.

Data

Summary

References

Data testing is done to confirm that the data itself is of high quality.

Tests include:

1. Confirming “reasonableness” of individual historical time series.
2. Comparing pricing sources for particular tickers.
3. Comparing values and histories of related tickers.
4. Investigating consistency compared to models.

Reasonableness:

- Reasonable number of outliers in historical time series.
- Values do not oscillate.
- Different pricing sources are in agreement.

Model analysis:

- Bonds whose OASs are outliers might be suspect.
- Futures and forwards can be compared.
- Curves can be stripped and checked for anomalies such as negative probabilities (CDS) or negative or spiking forward rates (IR).

Model risk management:

- Fastest growing area in finance.
- 3 components:
 1. Effective governance.
 2. Robust model development, implementation and use.
 3. Sound model validation practices.

Governance:

- Firm-wide respect for model risk – “Safety first”.
- Independent reporting lines.
- Auditing.
